

INTRODUCTION

Background: Selective serotonin reuptake inhibitors (SSRIs), the most commonly prescribed antidepressants (AD), may increase the risk of intracerebral hemorrhage (ICH) because of impaired platelet function.

Goal: We studied the proportion of stroke cases with ICH among AD users and non-users, and the rate of SSRI prescription at discharge in the Florida Stroke Registry (FSR).

HYPOTHESIS

Hypothesis: the proportion of stroke cases presenting with ICH will be higher for AD users than non-AD users.

METHODS

Setting: FSR is a voluntary stroke registry of Florida hospitals participating in the AHA's Get With the Guidelines-Stroke quality care improvement program.

Patients: 127,915 FSR stroke cases in 2010-2019 with information on AD use.

AD users: n=17,009, median age 74, IQR=19

Non-AD users: n=110,906, median age 72, IQR=21

Analysis: Multivariable logistic regression to evaluate the proportion of all stroke cases that were ICH among AD and non-AD users at admission and rates of prescribed SSRIs at discharge.

Covariates: age, race, history of hypertension, diabetes, oral anticoagulant use, antiplatelets, statins.

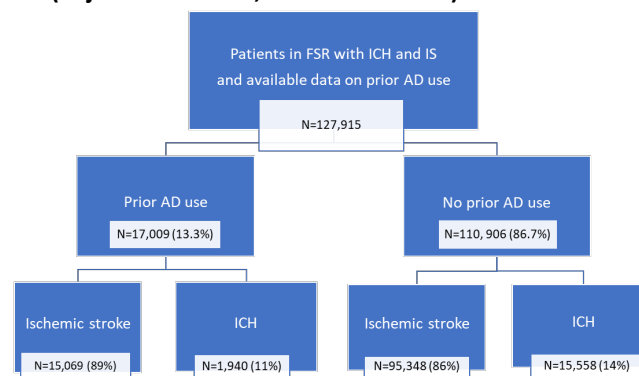

FUNDING

Funding provided by the Florida Department of Health, Funding # COHAN A1

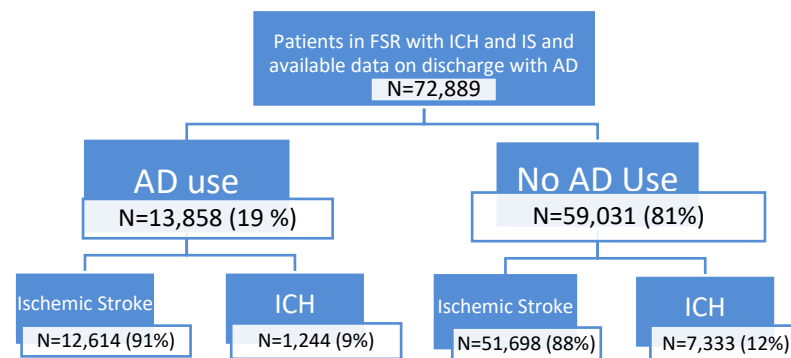

RESULTS

Prior AD users were more likely to be female, non-Hispanic White, have hypertension, diabetes, and use oral anticoagulants, antiplatelets, and statins.

AD users were just as likely to present with spontaneous ICH as compared to non-AD users (adjusted OR=0.92, 95% CI 0.85-1.01).

3.4% of ICH patients and 9% of those in whom AD information was available were discharged home on an AD (74% SSRI).

DISCUSSION

Hypothesized mechanism: By interfering with serotonin, which plays a role in blood clotting, SSRIs may increase the risk of bleeding.

Conclusion: These results do not support the hypothesis that SSRIs increase the risk of ICH specifically.

Limitations:

- All study participants were stroke cases, so we were unable to estimate the true risk of ICH among AD users and non-users.
- Details regarding the length, dosage and type of antidepressants were not available.

SUMMARY

- In this large population-based study, we did not find an association between prior AD use and an increased proportion of ICH among stroke cases.
- AD (mostly SSRIs) are commonly prescribed to patients with ICH in routine clinical practice.
- Randomized controlled trials are warranted to assess the safety of SSRIs in treatment of depression in patients with stroke.
